If I activate iGPU (enable internal graphic card in BIOS), that I will have kernel panic on system boot.

Normally FCPX shouldn't crash with only R9 280x activated

Yes, it's, But (perhaps) on fcpv<v. 10.4.

If I downgrade my system to 10.11 and fcpv to 10.3.4, that I also won't problems.

I tested to isolate hard disk's, OS and app moments - check disks with mhdd (bad blocks test), reinstall sierra as clean one, and check fcpv app. On real mac that one hadn't problems. A computer of my friend. Install that app on that mac - all're ok.

I can to test ram and other ones but why - As I'm and saying - El Capitan & fcpv 10.3.5 works great.

For good exploring I must to know, what log files I must to view. I can go over ssh to that OS, when I'm getting a frozen system (GUI). I must to know what I must to grep of that logs)If I will found that files).
