Ok, i try to tell it to you as easy as possible. Clover is the bootloader. You need Clover to start macOS. When you created the stick, you started the Clover installer and chose the USB drive as the destination where Clover shall be installed. So now you got Clover on the USB drive to start macOS. After that, you booted from the USB drive to install macOS. Now macOS is installed on the SSD, but the bootloader is not on the SSD. Just macOS... Thats why you still need the USB drive to boot macOS.

So all you have to do is install Clover on the SSD drive as well ! Its the same process when creating the Clover USB drive except this time when you start the Clover installer, you choose the **SSD drive as the destination.** After clover is installed on the EFI of the SSD, you take the files from the EFI of the USB drive and copy it to the EFI of the SSD. After that you can choose the SSD drive in the BIOS as boot media and you can start macOS without the USB drive.

I hope that I could explain it to you. I cant explain it easier.
