

Mac OSX mit AMD Prozessor

Beitrag von „fabiosun“ vom 11. April 2022, 18:01

AymanKraus

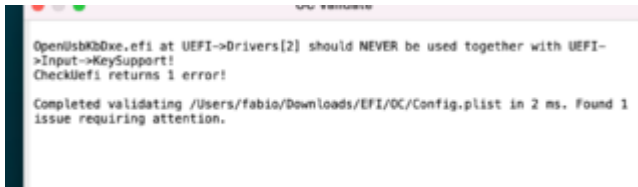

in this EFI you are using a quirk you shouldn't use:

DevirtualizeMMIO

Using this is useful (on AMD) on TRX40 chipset platform

Without declaring a proper MMIO Whitelist your system could have different problem (ie reboot, shutdown, wake/sleep and other)

You have also this little problem but it is not hard to solve

```
OpenUsbKbDxe.efi at UEFI->Drivers[2] should NEVER be used together with UEFI->Input->KeySupport!  
CheckUefi returns 1 error!  
Completed validating /Users/fabio/Downloads/EFI/OC/Config.plist in 2 ms. Found 1 issue requiring attention.
```

in my opinion you are using too much kext but if your system is fine maybe I am wrong! 😊

edit_

also this is a bit weird:

```
-v keepsym=1 debug=0x100 alcid=1 npcin=0x2000 agdmod=plkera UseKernelCaches=yes GraphicsEnabler=yes npcin=0x3000  
00000000
```
