AymanKraus

in this EFI you are using a quirk you shouldn't use:

DevirtualizeMMIO

Using this is useful (on AMD) on TRX40 chipset platform

Without declaring a proper MMIO Whitelist your system could have different problem (ie reboot, shutdown, wake/sleep and other)

You have also this little problem but it is not hard to solve

in my opinion you are using too much kext but if your system is fine maybe I am wrong! 😊

edit\_

also this is a bit weird:

Alles anzeigen

You're right. My failure with DevirtualizeMMIO. This should be False.

Also the added flags shouldn't be used:

UseKernelCache

GraphicsEnabler

npci=0x3000

Cleaned up the EFI a little bit and changed the wrong setting and deleted kexts.

Also you should add SMBIOS Serials for the iMacPro1,1 and your MAC Network address.
