No

Let me explain better even if between the two open threadsI got a bit lost

Your system is a great system for a hackintosh

It should work like a Swiss watch (that's our way of saying)

After we fixed the problem of incorrect patches you were using, I lost track of what you are installing

The kernel patches I put in an EFI allow you to work properly from High Sierra to Monterey (Monterey could be problematic for the problem that all MSIs below trx40 have with new bios and 5xxx series cpu)

If an EFI does not work for you during an early stage of the installation, you should always clean up the NVRAM before trying again.

For some in Monterey the setup had to be re-loaded if a direct update had been done

Very important for the new OS is the SecureBootModel item, for us AMD users it would be advisable to keep it on Default from when you start updating until the end

How the CPU is seen depends on the parameters that you have indicated and on the use of the kext always indicated above but it is not essential for proper functioning

You can write in CPU name whatever you want with the Kext and a parameter to put in NVRAM

To understand if your GPU is working at maximum, I would try some tests even old if you are on catalina like Cinebench r15 or luxmark
